Why Does the Channel Matter?

Separating Attention and Belief Mechanisms in Parental Information Interventions

Jordi Torres Vallverdú

MRes TSE — Behavioral Development Economics

March 2026

Outline

1. Introduction
2. Experimental Evidence
3. Mechanisms
4. Research Proposal
5. Model
6. Experimental Design
7. Identification
8. Power Calculations
9. Conclusion

Information Problems in Education

Students and parents make decisions under imperfect information

- Students hold biased beliefs about returns to education and own ability
  - Major choice and labor market outcomes [Arcidiacono et al., 2024, Wiswall and Zafar, 2015]
  - Persistence and dropout decisions [Stinebrickner and Stinebrickner, 2012, Arcidiacono et al., 2016]
  - College application and matching [Larroucau and Rios, 2026]
- **Parents are also misinformed** about their children's performance
  - Mean belief–performance gap > 1 SD in some contexts [Dizon-Ross, 2019]
  - Biases concentrated among low-SES households
- Parental investments respond to information $\Rightarrow$ misperceptions distort human capital accumulation

Information Treatments to Parents

Providing information to parents improves outcomes

- Dizon-Ross [2019]: Correcting beliefs about child ability in Malawi
  - Parents reallocate investments toward lower-performing children
  - Beliefs are systematically upward-biased
- Bergman [2021]: SMS-based grade notifications in the US
  - Parents receive same info via SMS vs. standard report cards
  - Result: 0.19 SD GPA increase at very low cost
  - $\sim$59% from belief revision, $\sim$41% from reduced monitoring costs
- **The puzzle:** the *channel* of delivery matters, not just content

Why Does the Channel Matter? Possible Mechanisms

Standard economics: only content should matter $\Rightarrow$ **three behavioral mechanisms**

1. **Biased beliefs & asymmetric updating**
   - Parents hold upward-biased priors; update asymmetrically
   - More information $\Rightarrow$ belief correction
2. **Limited attention & salience** $\leftarrow$ *main focus*
   - Under cognitive load, "child performance" drops out of active decision model [Gabaix, 2014]
   - SMS creates high salience contrast vs. report card among paperwork [Bordalo et al., 2012]
3. **Present bias & procrastination**
   - Parents intend to engage but delay; SMS reduces action delay

Problem: existing designs bundle content and channel $\Rightarrow$ cannot separate mechanisms

Research Questions

Goal: Disentangle the mechanisms behind parental information treatments

1. Does changing the *channel* alone (holding content fixed) affect parental behavior?
   $\Rightarrow$ Attention / salience mechanism

2. Does providing richer *content* (holding channel fixed) affect behavior?
   $\Rightarrow$ Belief correction mechanism

3. Are channel and content *complements* or *substitutes*?
   $\Rightarrow$ Interaction between attention and beliefs

4. Does *frequency* of contact matter beyond content and channel?
   $\Rightarrow$ Sustained attention vs. one-shot correction

Model: Production Function & Belief Updating

Grade production: Student i in school e:

$$Y_i = Y(a_i,\, e_i^p,\, e^s) + \varepsilon_i$$

- a_i: student ability $\quad e_i^p$: parental effort $\quad e^s$: school effort

Belief updating: Parents hold prior $\hat{a}_i^{\text{pre}}$, receive signal σ_i:

$$\hat{a}_i^{\text{post}} = \hat{a}_i^{\text{pre}} + \underbrace{A(\kappa_i)}_{\text{attention}} \cdot \underbrace{\lambda(\sigma_i, \hat{a}_i^{\text{pre}})}_{\text{salience}} \cdot (\sigma_i - \hat{a}_i^{\text{pre}})$$

- $A(\kappa_i) \in [0, 1]$: attention weight [Gabaix, 2014]
  - High cognitive load $\kappa_i \Rightarrow$ low attention; SMS lowers κ_i
- $\lambda(\cdot) \in [0, 1]$: salience weight [Bordalo et al., 2012]
  - Signals contrasting with priors get more weight

Model: Effort Choice

Parental effort: Given updated beliefs, parent maximizes:

$$\max_{e_i^p \geq 0} \ln Y(a_i,\, e_i^p,\, e^s)\Big|_{\hat{a}_i^{\text{post}}} - C^p(e_i^p,\, z_i)$$

- $C^p(e_i^p, z_i)$: cost of effort, heterogeneous in parent type z_i (SES, time)
- Allows credit constraints to enter through cost function

Key distinction:

- $A(\kappa_i)$: determines whether parent *considers* the information at all
- $\lambda(\cdot)$: determines how much weight the signal gets *conditional on attention*

$\Rightarrow$ Both needed: a parent can attend to a signal yet underweight it (or vice versa)

The RCT: Five Treatment Arms

Setting: Primary/secondary schools with digital gradebooks but low baseline parent–school communication. Randomization stratified by school characteristics.

Arm	Description	Channel	Content
C	Standard report cards (status quo)	Paper	Standard
T1	Same info, delivered via SMS/WhatsApp	SMS	Standard
T2	Detailed info (grades, ranking, absences)	Paper	Detailed
T3	Detailed info via SMS (replicates Bergman)	SMS	Detailed
T4	Same as T3, double frequency (weekly)	SMS	Detailed+

- T1 vs. C: isolates *channel* effect (attention)
- T2 vs. C: isolates *content* effect (beliefs)
- T3 vs. C: joint effect (replication of Bergman)
- T4 vs. T3: *frequency* / sustained attention

Identification Strategy

2×2 **factorial design** enables clean decomposition:

	Standard content	**Detailed content**
Paper channel	C	T2
SMS channel	T1	T3

revise. I think this is a bit off

Estimating equation:

$$Y_i = \alpha + \beta_1 \cdot \mathbf{1}[\text{SMS}]_i + \beta_2 \cdot \mathbf{1}[\text{Detailed}]_i + \beta_3 \cdot (\text{SMS} \times \text{Detailed})_i + X_i'\gamma + \epsilon_i$$

- β_1: attention effect A (channel changes, content fixed)
- β_2: belief-correction effect through $\lambda \cdot (\sigma - \hat{a})$
- β_3: complementarity between attention and beliefs

Additional: Elicit baseline beliefs $\hat{a}_i^{\text{pre}}$ to separate biased priors from distorted updating. T4 adds frequency dimension.

Power Calculations

Benchmark: Bergman [2021] finds 0.19 SD effect (joint treatment)

Assumptions:

- MDE = 0.10 SD (individual mechanisms smaller than joint effect)
- Significance level $\alpha = 0.05$, power $= 0.80$
- ICC $\rho = 0.05$ (school-level clustering), 20 students per cluster

Required sample (per arm):

$$n = \frac{(z_{1-\alpha/2} + z_{\text{power}})^2 \cdot 2\sigma^2 \cdot \text{DEFF}}{\text{MDE}^2} \approx \frac{(1.96 + 0.84)^2 \cdot 2 \cdot 1.95}{0.01} \approx 3{,}060$$

where DEFF $= 1 + (20 - 1) \times 0.05 = 1.95$ (design effect for clustering) **unfeasible**

- $\approx$ 3,000 students per arm $\times$ 5 arms = **15,000 students total**
- $\approx$ 750 school clusters (150 per arm)
- Stratification by school SES reduces variance

Conclusion & Policy Implications

Summary:

- Existing evidence: information treatments improve educational outcomes
- Open question: *why*—attention, beliefs, or their interaction?
- Proposed RCT with factorial design separates these mechanisms

Policy implications depend on the mechanism:

- If $\beta_1 \gg \beta_2$: channel/salience drives the effect $\Rightarrow$ invest in **nudge design**
- If $\beta_2 \gg \beta_1$: content/beliefs drive the effect $\Rightarrow$ **one-shot information** suffices
- If $\beta_3 > 0$: attention and beliefs are complements $\Rightarrow$ **both needed together**

Contribution:

- From reduced-form to structural understanding of why information works
- Low-cost, scalable interventions with large potential returns
- Framework generalizable to other informational settings in education
